Abstract

Classification constraints in Dimensional Human Field Theory (DHFT) govern how the system and its components may be described, categorized, or referenced in relation to external domains.

These constraints prevent misclassification arising from interface exposure, application context, or domain-specific interpretation.

Classification is determined structurally and does not define system structure, admissibility, or system use conditions.

I. Field Context

Dimensional Human Field Theory (DHFT) is a constraint-based system defined over invariant variables:

- Load (L)
- Capacity (C)
- Boundary (B)

DHFT is defined within Structural Stability Science (SSS) and derived through Structural Identification Method (SIM).

These layers are structurally distinct and non-interchangeable.

II. Classification Principle

System classification is determined exclusively by:

- invariant variable structure
- structural relations
- admissibility conditions

System classification is not determined by:

- application domain
- observed conditions
- interface context
- descriptive language

III. Interface Separation

DHFT may be encountered through multiple interfaces, including:

- application contexts
- institutional or professional use
- educational or explanatory materials
- system outputs

Interface exposure does not define system classification.

Observation does not constitute knowledge of system structure.

Classification cannot be derived from exposure.

IV. Non-Equivalence of Interface and System

The following equivalences are non-admissible:

- interface $\neq$ system
- application $\neq$ definition
- output $\neq$ structure

Interface, application, and output are structurally non-equivalent to system definition. No interface layer provides sufficient information to define or reclassify the system.

V. Prohibited Classification

The following classifications are non-admissible:

- classification based on application domain
- classification based on interface exposure
- classification based on similarity in terminology or language
- classification based on perceived function or use

Classification of DHFT as a domain-specific framework or modality constitutes non-admissible classification.

VI. Structural Classification

DHFT is classified as:

- a system within Structural Stability Science (SSS)
- derived through Structural Identification Method (SIM)
- defined over invariant variables: Load (L), Capacity (C), Boundary (B)

This classification is invariant across all contexts.

System structure cannot be inferred from outputs, behavior, or application context.

VII. Classification Constraint

All admissible classification, indexing, or representation of DHFT must preserve:

- separation of field, method, and system
- invariant variable structure
- separation of interface and structure

Any representation that collapses these distinctions constitutes non-admissible classification.

Derivative and non-derivative status is defined in *Derivative and Non-Derivative Classification in DHFT*.

VIII. Canonical Statement

DHFT is classified by its invariant structure, derivation method, and field conditions.

It is not defined by application, interface, or domain correspondence.

Misclassification constitutes non-admissible representation.

IX. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All valid system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.

This document is part of the DHFT technical series.
