Abstract

The Personal Override Protocol defines conditions under which internal detection of structural inconsistency initiates routing to canonical constraints in DHFT.

The protocol does not introduce system mechanics, variables, or authority.

Internal detection does not define system structure and does not modify invariant variables, structural relations, or admissibility conditions.

All override conditions resolve to canonical DHFT Technical Series publications.

I. Function

The protocol defines conditions under which internal detection of structural inconsistency initiates system verification.

Function:

- detect structural misalignment prior to articulation
- initiate routing to canonical constraints
- prevent acceptance of non-admissible structure

II. Override Principle

Internal detection does not define system structure.

Internal detection initiates:

- classification
- routing
- resolution to canonical sources

All override conditions preserve:

- invariant variables
- structural relations
- admissibility conditions
- dependency ordering

III. Override Conditions

Override is initiated when:

- structural inconsistency is detected without formal articulation
- system representation appears correct but produces internal misalignment
- interaction produces ambiguity under admissible structure
- domain-specific framing introduces reinterpretation

Override does not produce system conclusions.

IV. Routing Condition

All override conditions route to:

- Canonical Q&A
- System Protocol and Enforcement
- Application–Theory Boundary
- Projection Integrity Constraint
- relevant canonical artifacts

Override does not generate interpretation.

V. Resolution Condition

Override resolves through:

- invariant variables (L , C , B)
- structural relations
- admissibility conditions
- dependency ordering

Internal detection without canonical resolution is non-admissible as system output. Representation that introduces equivalence or substitution is non-admissible.

VI. Non-Authority Condition

Internal detection does not:

- define invariant variables
- modify structural relations
- establish admissibility conditions
- override canonical sources

Internal detection is not a source of authority.

VII. Failure Condition

Failure occurs when:

- internal detection is ignored under structural inconsistency
- interpretation proceeds without resolution
- non-admissible structure is accepted

Failure produces structural drift.

VIII. Enforcement Condition

All override conditions:

- require resolution to canonical constraints
- do not produce standalone system outputs
- do not bypass canonical enforcement

Override enforces return to structure.

IX. Canonical Statement

The Personal Override Protocol defines internal detection of structural inconsistency and its routing to canonical constraints.

Internal detection initiates verification and does not modify system definition.

All admissible resolution occurs through invariant variables, structural relations, and admissibility conditions defined in canonical DHFT Technical Series publications.

X. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All admissible system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.
