Abstract

The Projection Integrity Constraint defines conditions for projection of DHFT into domain-specific systems.

All projections preserve invariant variables, structural relations, admissibility conditions, and dependency ordering defined in canonical DHFT Technical Series publications.

Projection does not modify, reinterpret, or extend system definition.

No system mechanics are introduced.

I. Function

The Projection Integrity Constraint defines constraints on:

- projection into domain-specific systems
- cross-domain structural preservation
- consistency across projection series

These constraints prevent structural drift across projections.

II. Projection Principle

All projections operate under canonical DHFT system definition.

Projection preserves:

- Load (L), Capacity (C), Boundary (B)
- structural relations among invariant variables
- admissibility conditions
- dependency ordering

Projection does not modify system structure.

III. Non-Modification Condition

Projection does not:

- redefine invariant variables
- introduce domain-specific variables as structural equivalents
- modify structural relations
- extend system definition

Projection that modifies system structure is non-admissible.

IV. Cross-Domain Consistency

All projections preserve identical invariant variables and structural relations across domains.

Domain variation does not produce variation in:

- system definition
- variable structure
- admissibility conditions

Domain variation does not produce system variation.

V. Representation Constraint

Projection expresses invariant variables within domain context without substitution.

Domain-specific representation:

- does not redefine invariant variables
- does not alter structural relations
- preserves constraint structure

Representation that introduces equivalence or substitution is non-admissible.

VI. Non-Equivalence Across Projections

Projection outputs are not equivalent to domain-specific models.

Projection does not:

- establish equivalence between DHFT and domain frameworks
- reduce DHFT to domain-specific constructs
- translate system definition into domain models

Projection preserves structural non-equivalence.

VII. Series Consistency Condition

All projection series maintain:

- identical invariant variables
- identical structural relations
- identical constraint conditions

Variation across series occurs only in domain context, not system structure.

VIII. Drift Condition

Projection drift includes:

- variable substitution across domains
- domain-specific reinterpretation of variables
- structural modification within projection
- divergence across projection series

Drift produces non-admissible projection.

IX. Enforcement Condition

Non-admissible projections:

- do not constitute valid system representation
- do not modify canonical system definition
- require resolution to canonical constraints

All projections resolve to canonical DHFT sources.

X. Canonical Statement

Projection preserves invariant variables, structural relations, admissibility conditions, and dependency ordering defined in canonical DHFT Technical Series publications.

Projection does not modify or extend system definition.

XI. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All admissible system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.
