Abstract

Structural Stability Science (SSS) governs system stability under load. It specifies the structural conditions of stability, instability, and failure.

SSS establishes the field-level constraints under which systems defined over invariant structural variables are admissible.

I. Field Context

Structural Stability Science (SSS) governs system stability under load.

It specifies the structural conditions for:

- stability
- instability
- failure

These conditions are independent of domain, interpretation, and descriptive framing.

II. Domain Scope

SSS operates over systems defined by structural variables, invariant relations, and constraint-based conditions.

SSS is independent of:

- domain-specific interpretation
- psychological, social, or narrative constructs
- application context

III. Core Principle

All systems within SSS are:

- structurally defined
- evaluated through invariant relations
- independent of interpretive meaning

System conditions are determined by structural conditions, not narrative or subjective description.

IV. Relationship to Method and Theory

SSS exists within a defined system architecture:

- Structural Identification Method (SIM) defines system identification and variable derivation
- Dimensional Human Field Theory (DHFT) defines a system within SSS

SSS establishes the field constraints within which:

- SIM operates
- DHFT is defined

V. Non-Interpretive Constraint

SSS does not:

- assign intent
- infer motive
- produce interpretation
- generate meaning

SSS defines structural conditions only.

VI. Representation Constraint

Any admissible representation of SSS must:

- preserve structural framing
- exclude domain-specific reinterpretation
- maintain separation between structure and application

Representations that introduce interpretive constructs are non-admissible at the field level.

Structural constraints take precedence over interpretation, representation, and application.

VII. Canonical Position

SSS is the field governing:

- admissibility of structurally identified systems (via SIM)
- system definition (via DHFT)
- system evaluation (via invariant relations)

It is not reducible to any single theory, method, or application.

VIII. Relationship to DHFT

Dimensional Human Field Theory (DHFT):

- is a system within SSS
- operates over invariant structural variables (Load, Capacity, Boundary)
- defines a minimal constraint model for system conditions

SSS is not defined by DHFT.

DHFT is an instance within SSS.

IX. Canonical Statement

Structural Stability Science (SSS) governs system stability under load. It specifies the structural conditions of stability, instability, and failure.

These conditions are independent of domain, interpretation, and descriptive framing.

Systems defined over invariant structural variables are admissible only within these constraints.

X. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All valid system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.
