Abstract

This note defines the mechanics governing jurisdiction, authorization, and derived authorization within Dimensional Human Field Theory (DHFT). These mechanics specify admissibility, gating, and propagation conditions within a system.

All definitions are structural, non-interpretive, and invariant under scope closure.

0 Definition of DHFT

Dimensional Human Field Theory (DHFT) is a structural system that defines invariant relations governing human behavior across individuals, organizations, and institutions.

DHFT operates on non-interpretive variables and specifies the conditions under which systems stabilize, destabilize, or propagate.

The theory is non-psychological and non-moral. It does not rely on intention, interpretation, or narrative. System behavior is determined by structural relations under constraint.

DHFT is organized as a dual architecture consisting of Dimensional Human Physics (DHP), which governs system dynamics, and Dimensional Self Architecture (DSA), which governs identity continuity and persistence.

1 Purpose

Admissibility, authorization, and propagation are structural.

These mechanics operate on load, capacity, and boundary permeability.

No additional variables are introduced.

Expanded derivations and domain-specific applications appear in subsequent preprints and texts.

These mechanics operate on load that has already been registered within the system; they do not define the conditions under which load is detected or enters the system.

2 Jurisdiction Mechanics

Jurisdiction mechanics define the admissible space of transformations available to a system.

Admissibility is determined by system state across load, capacity, boundary permeability, and time.

Jurisdiction specifies what can occur.

It does not determine whether occurrence takes place.

Non-Substitutability

- legal jurisdiction
- authority
- permission
- consent
- role or entitlement

Jurisdiction is structural admissibility.

3 Authorization Mechanics

Authorization mechanics determine whether a transformation propagates within the admissible space.

Authorization is a structural gating function.

Authorization is determined by system state, including load distribution, capacity margins, boundary permeability, and identity modulation.

Authorization is not granted, revoked, or negotiated.

Authorization is a condition of constraint alignment.

Authorization does not define identity structure; it operates within constraints imposed by identity architecture.

4 Derived Authorization

Derived authorization is the observable outcome of authorization mechanics.

- propagation
- resistance
- redirection
- collapse

Derived authorization is not a mechanism.

Derived authorization reflects system response and cannot be used to infer upstream authorization conditions.

5 Structural Conditions

Jurisdiction mechanics and authorization mechanics operate on:

- $L(t)$
- $C(t)$
- $B(t)$

No additional variables are introduced at this layer.

6 Domain Separation

These mechanics operate within DHFT and are continuous with Dimensional Human Physics (DHP).

Dimensional Self Architecture (DSA) modulates system configuration but does not redefine load, capacity, or boundary permeability.

Cross-domain reinterpretation is not permitted.

7 Non-Collapse Conditions

Authorization operates within jurisdiction.

Jurisdiction is constrained by system state.

Derived authorization is not intention, consent, or decision.

Authorization is not authority, permission, or legitimacy.

Jurisdiction is not social, legal, or institutional designation.

8 Scope Closure

All mechanics are structural and non-interpretive.

All downstream use preserves:

- variable definitions
- domain separation
- structural invariance
