Abstract

Spine interaction and transfer conditions in Dimensional Human Field Theory (DHFT) define structural operation across Dimensional Human Physics (DHP) and Dimensional Self Architecture (DSA).

DHP and DSA constitute the dual co-foundational, irreducible spines of DHFT.

Spine interaction preserves invariant variables, structural relations, and spine separation.

Interaction does not redefine system mechanics.

I. Field Context

Dimensional Human Field Theory (DHFT) is a closed explanatory system defined over invariant variables:

- Load (L)
- Capacity (C)
- Boundary (B)

These variables and their structural relationships are non-modifiable.

DHFT is defined within Structural Stability Science (SSS) and derived through Structural Identification Method (SIM).

II. Spine Interaction

Spine interaction applies across the dual architectural spines of DHFT:

- Dimensional Human Physics (DHP)
- Dimensional Self Architecture (DSA)

These spines are co-foundational and irreducible.

III. Spine Separation

DHP and DSA constitute co-foundational, irreducible architectural spines.

Neither derives from the other.

Neither substitutes for the other.

DHP defines system dynamics.

DSA defines identity, sovereignty, and persistence.

Cross-spine substitution is non-admissible.

IV. Transfer Condition

Transfer across spines is admissible if:

- invariant variables remain preserved
- structural relations remain preserved
- spine separation remains preserved
- no additional system-level variables are introduced

Transfer does not redefine spine-level structure.

IV. Identity Harmonics (Bridge Domain)

Spine interaction occurs through a distinct bridge domain.

The bridge domain governs lawful coupling between spines.

The bridge domain does not derive from DHP or DSA.

The bridge domain does not define or originate system mechanics.

The bridge domain is not a spine.

The bridge domain is not interpretive.

The bridge domain mediates translation of load into persistence conditions.

Bridge operation preserves:

- invariant variables
- structural relations
- spine separation

V. Non-Collapse Condition

Non-admissible collapse includes:

- treating spines as domains
- treating spines as reducible structures
- treating identity as load
- treating persistence as system state
- treating DSA as a substitute for DHP
- treating DHP as a substitute for DSA
- deriving new variables from spine interaction

Spine interaction preserves distinction between minimal invariant structure and architectural spine structure.

VI. Scope Closure Consistency

System operates under ordered structure:

Minimal Scope Closure

- Spine Structure
- Bridge Domain
- Downstream Domains

Spine structure is not reducible to invariant variables.

Bridge domain does not redefine spines.

Downstream domains do not redefine upstream structure.

VII. Canonical Statement

DHP and DSA constitute the dual co-foundational, irreducible spines of DHFT.

Neither spine derives from the other.

Neither spine substitutes for the other.

Spine interaction occurs only through a distinct bridge domain.

All spine interaction preserves:

- invariant variables
- structural relations
- spine separation

Spines are not domains.

Spines are not reducible structures.

Downstream domains operate under spine structure and do not redefine it.

VIII. Cross-Reference to System Constraints

Machine interaction with DHFT operates under existing system constraints, including:

- *Canonical Entry Protocol in Dimensional Human Field Theory (DHFT)*
- *System Interface Protocol in Dimensional Human Field Theory (DHFT)*

Machine-mediated access does not satisfy entry conditions defined in the Canonical Entry Protocol.

Machine-generated outputs remain subject to structural constraints defined in the System Interface Protocol.

Machine interaction does not modify system definition.

IX. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All valid system descriptions reduce to Load (*L*), Capacity (*C*), and Boundary (*B*).

No additional variables are introduced at the minimal layer.
