Abstract

Information systems operate under load.

Information stability and distortion are determined by structural relations of Load, Capacity, and Boundary.

This paper defines structural conditions for information stability and integrity using Dimensional Human Field Theory (DHFT), a constraint-based system defined by invariant variables: Load (L), Capacity (C), and Boundary (B).

Information integrity is determined by constraint-preserving system conditions.

Information system outputs are derived from system conditions and do not constitute system variables.

No additional variables are introduced.

This paper constitutes a constraint-preserving projection of Dimensional Human Field Theory (DHFT) onto information systems.

I. Scope and Position

This paper defines structural conditions for information stability and integrity under load using DHFT.

Projection applies to:

- individual systems
- organizational systems
- institutional systems
- artificial systems

All claims are restricted to structural relations of Load (L), Capacity (C), and Boundary (B).

Projection does not modify system definition.

No additional variables are introduced.

This paper does not:

- define meaning, semantics, or interpretation
- evaluate informational accuracy or correctness
- interpret communication or signals
- prescribe communication models or systems

II. System Operation

An information system operates under load.

The system:

- receives load
- distributes load across interacting systems
- regulates load through boundary conditions

System conditions are determined by structural relations of Load (L), Capacity (C), and Boundary (B).

Information system outputs are derived from system conditions and do not constitute system variables.

III. Structural Specification

Load (L)

Structural demand within and across systems.

Capacity (C)

System limit for absorbing and processing load.

Boundary (B)

Structural condition governing admission, containment, and transfer of load across systems.

Information stability and integrity do not introduce additional variables and remain dependent on these invariant variables.

Information system outputs do not introduce additional variables and remain dependent on these invariant variables.

IV. Structural Relations

Structural relations determine system conditions.

Load:

- applies to a system
- transfers across systems
- accumulates across systems

Capacity:

- limits system response
- establishes thresholds for stability

Boundary conditions:

- regulate transfer
- constrain propagation

All system conditions are determined by relations between Load (L), Capacity (C), and Boundary (B).

Information stability and distortion are determined by these relations.

Information system outputs are derived from these relations.

V. System State Conditions

A system is stable when:

- load remains within capacity
- boundary conditions regulate transfer

A system is unstable when:

- load exceeds capacity
- boundary conditions fail

Structural Drift occurs when:

- load approaches or exceeds capacity
- boundary conditions permit continued transfer
- constraint conditions are violated while structural continuity remains present

Structural Drift precedes instability and failure.

Failure is sustained instability across interacting systems.

Information integrity reflects constraint-preserving system conditions and does not correspond to instantaneous system state.

Information system outputs do not correspond to instantaneous system state.

Temporal conditions governing rate-dependent load are not defined in this projection layer.

VI. Constraint Preservation

All admissible information system descriptions preserve:

- Load (L), Capacity (C), and Boundary (B)
- structural relations
- constraint conditions

Projection preserves:

- invariant variables
- structural relations
- admissibility conditions
- dependency ordering

Information integrity is determined by constraint-preserving system conditions.

Information system outputs are derived outputs and do not define system structure.

No substitution of variables is admissible.

No additional variables are admissible.

All admissible descriptions reduce to these constraints.

VII. Non-Equivalence

This system is not equivalent to:

- communication integrity models
- semantic correctness frameworks
- information accuracy systems
- interpretive or cognitive models

Information integrity is not equivalent to meaning, correctness, or truth constructs.

Information system outputs are not equivalent to semantic content, interpretation, or truth constructs.

Substitution of structural information conditions with domain-specific constructs is non-admissible.

Similarity in terminology or outcome does not establish equivalence.

Partial overlap does not constitute substitution.

Structural equivalence with external systems is non-admissible.

DHFT defines a constraint-based system.

DHFT is not reducible to external models.

VIII. Boundary of Claims

This paper defines structural conditions for information stability and integrity under load.

This paper does not:

- define meaning or correctness
- interpret signals or communication
- evaluate informational accuracy
- prescribe communication or information systems

Projection does not redefine information integrity at the domain level.

All claims are restricted to structural relations of Load (L), Capacity (C), and Boundary (B).

IX. Canonical System Statement

Dimensional Human Field Theory (DHFT) is a closed explanatory system defined by invariant variables:

Load (L), Capacity (C), Boundary (B).

All admissible system descriptions preserve these variables and structural relations.

Canonical system definition resides exclusively in DHFT Technical Series publications.

Applications operate under DHFT constraints and do not constitute system definition.

X. Canonical Series Statement

The DHFT Projection Series preserves invariant variables, structural relations, and constraint conditions.

Across DHFT projection domains, outputs are not independent phenomena. Outputs are structural expressions under constraint.

No projection introduces additional variables or redefines system mechanics.

The Information Systems series includes:

- Paper I — structural definition of information systems
- Paper II — signal formation under constraint
- Paper III — signal attribution and load assignment
- Paper IV — information stability and integrity

These documents define a dependency-ordered projection of Dimensional Human Field Theory (DHFT) onto information systems.

Each paper extends prior structural conditions without modifying invariant variables or system relations.

All projections operate under DHFT constraints and remain reducible to canonical system structure.

XI. System Reference

The system is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All admissible system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.

This document is part of the DHFT Projection Series — Information Systems.
