Abstract

Structural Recovery is a required phase under conditions where capacity is restored, accumulated load is reduced, and boundary conditions stabilize.

This document defines recovery as a structural condition of system behavior, not an optional or interpretive process.

I. Scope

This document defines Structural Recovery as a phase of system operation under conditions of accumulated load. It specifies the role of recovery in maintaining capacity and structural integrity under load.

No interpretive or application-layer constructs are introduced.

II. Definition

Structural Recovery is a phase under structural conditions where capacity is restored, accumulated load is reduced, and boundary conditions stabilize.

Structural Recovery is not absence of activity. It is required for continued coherent function under load.

III. Load Context

Under sustained structural conditions of load accumulation, previously received load continues to be processed after external demand decreases.

Load persists as a function of prior exposure, rate, and accumulation over time.

IV. Core Principle

Sustained load conditions without capacity restoration result in reduced structural integrity.

V. Structural Effects

Structural Recovery is characterized by the following effects:

Capacity Increase

Capacity is increased.

Load Reduction

Accumulated load is reduced.

Boundary Stabilization

Boundary conditions are stabilized.

VI. Misclassification

Structural Recovery is misclassified as reduced output or system instability under incomplete measurement of structural conditions.

Misclassification results in re-entry into load conditions under unresolved constraints.

VII. Architectural Framing

Structural Recovery occurs under conditions in which:

- Load (L) exceeds optimal range
- Capacity (C) is reduced
- Boundary (B) conditions permit continued accumulation

Under recovery conditions, load decreases, capacity increases, and boundary conditions stabilize.

VIII. Statement

Structural Recovery is a required phase of system behavior under load. Capacity is restored, boundary conditions stabilize, and structural continuity is preserved.

IX. System Reference

The system defined in this document is specified in:

Dimensional Human Field Theory (DHFT): Architectural Identification of a Closed Explanatory System

DOI: 10.5281/zenodo.19075948

All valid system descriptions reduce to Load (L), Capacity (C), and Boundary (B).

No additional variables are introduced at the minimal layer.

This document is part of the DHFT technical series.
